Abstract

Governments often insulate authority over costly and controversial healthcare funding decisions from day-to-day electoral politics, relying on technical assessments and objective criteria to justify those decisions. Yet public responses to these decisions remain highly sensitive to how identical choices are presented. This article examines whether institutional insulation constrains framing effects on mass preferences, or whether citizens' evaluations of state funding decisions remain elastic to framing even when authority is formally insulated from electoral politics. Drawing on prospect theory, we argue that preferences over healthcare spending are reference-point dependent, such that citizens respond differently when funding decisions are framed as avoiding salient losses versus preserving existing gains. We test this argument using a population-based survey experiment embedded in the 2021 Finnish Medicines Barometer, in which respondents evaluate an identical clinical vignette involving a novel, high-cost cancer medicine with uncertain benefits and are randomly assigned to alternative frames emphasizing last-resort rescue or stewardship of finite collective resources. Holding clinical evidence, costs, and uncertainty constant, we find substantial and systematic framing effects on mass preferences over public funding. Support for funding increases when decisions are framed as loss avoidance and decreases when framed as gain preservation, despite identical policy content. These findings demonstrate that institutional insulation from electoral politics does not neutralize framing effects on mass preferences. Instead, decisions justified through technical criteria remain politically consequential because public communication and interpretive frames shape how citizens evaluate distributive choices. By integrating research on framing with the political economy of delegation, this article explains why distributive healthcare policies remain politically contested even when citizens are not the formal decision-makers and highlights the behavioral foundations of public responses to state action under conditions of risk, scarcity, and institutional insulation.

Abstract length: 283 words.

PLEASE DO NOT CIRCULATE.

Keywords— framing effects; healthcare rationing; delegation; mass preferences; political economy.

1 Rationing, delegation, framing and Mass Preferences in health-care context

All health systems must set priorities in order to allocate scarce fiscal, personnel, and other medical resources. Rationing occurs when potentially beneficial interventions are withheld from individuals (Scheunemann and White 2011). Rationing in healthcare is highly political and is characterised by moral and ethical dilemmas, as well as conflicting values and interests (Baeroe and Baltussen 2014; Baltussen et al. 2016). Mass preferences over high-cost healthcare rationing present a democratic puzzle.

In democracies where funding for healthcare and other public goods is predominantly raised through taxes or tax-like contributions, politics is the main arena for debating the underlying values that guide prioritisation and rationing. However, authority over high-cost and controversial treatment decisions is commonly insulated from day-to-day electoral politics, for example by delegating reimbursement decisions to lower levels of government or to specialised arm's-length agencies that employ applied methods, such as health technology assessment (HTA), to inform decision-making (Egeberg et al. 2009; EC 2018). Nevertheless, rationing decisions always involve value judgements, either explicitly or implicitly embedded in the assessment procedures used (Clark and Weale 2012). For example, HTA frequently includes cost-effectiveness or cost-utility analysis as an evaluation method, the selection of which already reflects a normative commitment to health maximisation as a prioritisation criterion (Jansen et al. 2017; Daniels and van der Wilt 2016).

The replacement or complementing of traditional political institutions by such arrangements could be blamed for blurring democratic control, accountability, and legitimacy (Peters and Pierre 2004). The uptake of innovative pharmacotherapies represents an illustrative example. In Europe, the supranational EU regulatory framework, oriented towards facilitating industrial policy goals (Permanand and Mossialos 2005; Permanand et al. 2006), has led to many new therapies entering markets with limited evidence for their therapeutic value (Hwang et al. 2020; Vella Bonanno et al. 2017). A recent development is the regulation on HTA (EU HTA R (EU)2021/2282), aiming to harmonise and accelerate HTA processes across the member states (Brinkhuis et al. 2024). At national and subnational levels, governments manage the economic risks involved through confidential arrangements with industry (Barrenho and Lopert 2022; Wenzl et al. 2019).

It is widely held that priority setting should be pursued through a framework that engages all relevant stakeholders (Daniels and Sabin 2008; Baeroe and Baltussen 2014; Aidem et al. 2017; Jansen et al. 2018, 68–72). In decisions concerning funding of novel pharmacotherapies, confidentiality, technical complexity, and practical reasons often prevent payers from consulting all stakeholders or disclosing and disseminating the rationales behind decisions to them (Barrenho et al. 2022; Mitton et al. 2006; Kapiriri and Razavi 2017). Thus, decision-making processes recede from the qualities associated with legitimacy (Daniels and Sabin 2008; Daniels and van der Wilt 2016).

Yet decisions are still communicated to and evaluated by citizens. Previous evidence from high-income countries suggests that mass preferences over prioritisation criteria display substantial elasticity in response to how choices are presented and justified. Citizens may not recognise the need to prioritise; they may express conflicting preferences and priorities and value different prioritisation criteria than public payers (Blendon et al. 2012; Owen-Smith et al. 2009; Diederich and Salzmann 2015; Desser et al. 2010; Desser et al. 2013; Ghinea et al. 2021; MacLeod et al. 2016). This elasticity raises an important question: Does institutional delegation insulate these decisions from framing effects, or do citizens' preferences continue to shift with how decisions are framed even when authority is formally insulated from electoral politics?

This article suggests that mass preferences remain elastic to framing effects: preferences over

healthcare funding decisions are reference-point dependent regardless of institutional insulation. Even when clinical evidence, costs, and uncertainty are held constant, citizens' support for expensive medicines changes substantially depending on whether the decision is presented as avoiding a salient loss—withholding a last-resort option from an identifiable patient—or as preserving existing gains by protecting finite fiscal resources from extraordinary expenditure. We find that insulating decision-making from electoral politics does not eliminate the contestability of distributive choices; rather, it reorganizes contestation around public communication and the interpretive frames through which citizens evaluate state action.

Our findings have important implications. Such healthcare policies remain politically contentious not because decisions are justified using allegedly objective technical and scientific criteria rather than political judgment, but because mass preferences remain anchored to loss-versus-gain framing and to rescue narratives that can be activated—or dampened—through how choices are presented to the public. In the pharmaceutical sector, an additional factor is the intervention of well-resourced industry lobbies, capable of deploying costly strategies to pursue and protect their interests (Greer et al. 2016). Conflicts over prioritisation have manifested as critical debates in the media (Abelson et al. 2009; Corbett and Mori 1999), which can be a powerful driver of public opinion (Gabe et al. 2012; Aggarwal et al. 2017; Pinho et al. 2020).

The experiences of the NHS Cancer Drugs Fund in England provide an example of the consequences of such conflicts. The fund was created in response to public and political pressure to finance cancer medicines that the National Institute of Health and Care Excellence (NICE) had not recommended on the basis of its assessment criteria. An evaluation conducted five years after its establishment found no meaningful benefit to patients or society, when measured in terms of survival, quality of life, or toxicity, and suggested potential societal harm once opportunity costs were taken into account (Aggarwal et al. 2017).

Extraordinary costs of new oncology medicines challenge health systems globally. In the Nordic countries, cancer medicine costs increased between 2012 and 2017, with growth rates ranging from 37 to 125 percent, being the fastest-growing cost element of cancer care. Torkki et al. (2022) also document pronounced cross-national differences in cost structures and cost drivers, reflecting variation in the organization of care and health policy priorities. Similar dynamics extend beyond Europe. Using U.S. data, Nguyen et al. (2025) report that very high-cost users tend to live in areas with higher social needs and that conditions such as cancer account for a disproportionate share of expenditures, underscoring the distributive and political dimensions of high-cost care.

These pressures are compounded by scientific uncertainty: novel oncology drugs often enter reimbursement debates with limited evidence on long-term survival or quality-of-life effects, while the fiscal implications of public funding are immediate (Cohen 2017). As Aziz et al. (2020) illustrate, marginal expected health gains are frequently paired with exceptionally high costs. Overall, retrospective analyses of novel cancer medicines approved through accelerated access pathways suggest limited added clinical benefits (Davis et al. 2017; Brinkhuis et al. 2024).

This context generates an important tension between the principles that structure how funding decisions are made and how citizens evaluate these decisions, thus providing substantive terrain on which framing mechanisms operate.¹ One logic emphasizes stewardship: because healthcare budgets

¹At a structural level, these choices resemble classic problems in distributive politics, where public funds are allocated to projects with concentrated benefits and diffuse costs, such as geographically targeted infrastructure spending (Weingast, Shepsle, and Johnsen 1981). However, healthcare rationing differs in a crucial respect: while residence in a remote island is largely a matter of choice, exposure to severe illness is fundamentally uncertain and broadly shared. As a result, citizens evaluating cancer medicines may support high-cost spending not because they benefit directly today, but because they recognize a latent personal risk of future need—an intertemporal logic that distinguishes healthcare from standard pork-barrel allocations.

are finite, publicly financed systems require allocating resources in ways that sustain broad access and protect population health. The other logic emphasizes rescue: when a specific patient faces imminent death and a treatment offers even a small chance of benefit, refusing to act is experienced as a morally troubling choice. This intuition is captured in the “rule of rescue,” which McKie and Richardson (2003, p. 2407) define as the imperative people feel to rescue identifiable individuals facing avoidable death. “This imperative entails a preference for identifiable over statistical lives, the shock-horror response it elicits, and the preference it entails for lifesaving over non-lifesaving measures.” In cancer care, these intuitions are repeatedly activated because patients are identifiable, prognoses are often stark, and clinical narratives translate easily into public dramas of avoidable loss. At the same time, these decisions are unavoidably distributive: the opportunity costs of funding one medicine are borne by anonymous others, and citizens must assess whether collective resources have been allocated appropriately.

Existing research indicates that citizens can engage with these trade-offs, yet their expressed preferences are conditional on how decisions are presented and justified. Deliberative exercises suggest that publics can accept scarcity and the need for thresholds under certain procedural conditions. In British Columbia, Bentley et al. (2018) find that participants accepted the principle of resource scarcity and the need for governments to make difficult trade-offs when allocating healthcare resources, and supported the view that cost-benefit thresholds must be set for high-cost drugs. Participants also expected reasonable health benefits in return for large expenditures and supported the view that some drugs do not merit funding. Survey evidence from other contexts reveals similar conditionality. For example, Noh and Son (2025) report that three-quarters of respondents supported reimbursement of high-cost cancer drugs, but that support depended on confidence that drugs were safe, effective, and cost-effective.

However, mass political attitudes under conditions of constraint are highly elastic to how choices are presented. A broad literature on framing demonstrates that preferences over public spending are malleable. In Ghana, Smith et al. (2025) suggest that support for health taxes increased when these taxes were framed as improving public health or promoting fairness. Similarly, Jones (2022) argues that healthcare policy evaluation necessarily depends on which considerations are made salient. Importantly, others suggest that framing alters how risks and outcomes are interpreted. For example, Kahneman and Tversky (1984) suggest that preferences vary markedly when identical outcomes are framed in terms of losses rather than gains. Related work suggests that frames shape mass policy attitudes in other domains, including food regulation (Roh and Niederdeppe 2016) and medical debt (McCabe 2023). During COVID-19, Valenzuela et al. (2021) document how competing frames shaped support for restrictive policies, with exposure to both economic and public health frames reducing support for mobility restrictions.

Taken together, these literatures motivate an interpretation of mass preferences in delegated healthcare rationing that emphasizes reference points, perceived losses, and asymmetric responses to risk. Prospect theory establishes that individuals evaluate choices relative to reference points and exhibit loss aversion, becoming risk-seeking when choices are framed in the loss domain and risk-averse when framed in the gain domain (Kahneman and Tversky 1979; Vis 2011). Applied to healthcare rationing, this predicts that when a contested funding choice is framed as avoiding a salient loss—for example, by emphasizing withholding a last-resort option from an identifiable patient—prospect theory predicts citizens should be more willing to endorse riskier and more expensive options to avert that loss (Hameleers 2020). Conversely, when the same choice is framed as protecting existing gains—safeguarding finite fiscal resources from extraordinary expenditure—citizens should favor restraint (Hameleers 2020).

The key question our paper posits is whether these framing effects persist when such decisions are justified through technical criteria and communicated to citizens in contexts where authority

is formally insulated from electoral accountability. Delegation is commonly narrated as a route to depoliticization, in which evidence is assessed through objective criteria, thresholds are applied consistently, and distributive choices are presented as technically grounded rather than politically discretionary (**Thatcher2002**). In many contemporary healthcare systems, including Finland, citizens are not asked to decide directly on reimbursement but are routinely exposed to funding decisions that are justified in precisely these technical terms, making public interpretation of such decisions politically consequential even under delegation. Yet if mass preferences are systematically sensitive to loss-versus-gain frames (**Laenen2025**), then institutional insulation from electoral politics may not eliminate contestation. Instead, contestation may be reorganized around how decisions are communicated and the interpretive frames through which citizens evaluate state action—shifting from political contestation to contestation over meaning and narrative authority.

This implication connects to debates on delegation and accountability, where responsibility for policy outcomes becomes a central object of political contestation. Existing work suggests that delegation is often assumed to allow governments to manage electoral pressures by shifting responsibility for unpopular decisions, but that this effect is conditional. For example, Heinkelmann-Wild et al. (2023) suggest that delegation can facilitate blame avoidance only under specific institutional designs, while Heinkelmann-Wild and Zangl (2020) suggest that the redirection of political pressure depends on whether citizens believe governments can credibly deny responsibility for outcomes. Delegation can therefore redistribute political pressure, but it does not eliminate contestation. In parallel, research on the contestability of expertise highlights that public responses to decisions justified using expert analysis cannot be explained by technical merit alone. As Head (2024) argues, expert policy advice is increasingly challenged by diverse actors, making the interpretation of state action central.

This paper proceeds as follows. section 2 explains our theory, focusing on how prospect theory and the rule of rescue operate in delegated healthcare rationing.

2 Theoretical Framework: Prospect Theory and the Rule of Rescue in Delegated Healthcare

In many affluent democracies, including Finland, decisions about whether to reimburse novel and expensive medicines are formally delegated away from day-to-day electoral politics and justified through technical criteria, such as health technology assessment. Although citizens are not asked to decide directly on reimbursement, they are routinely exposed to these decisions. Their evaluations of whether state action is acceptable, fair, and legitimate can, in turn, have consequences in terms of political and institutional trust, willingness to pay taxes and other contributions, confidence in the health system, and patterns of uptake of supplementary private insurance as a response to perceived access failures.

The central claim of this article is that delegation of authority (and the accompanying reliance on technical justifications) does not neutralize framing effects in mass opinion because it does not alter the cognitive mechanisms through which citizens evaluate distributive trade-offs. Instead, such delegation reorganizes contestation around public interpretation: when citizens encounter technically justified decisions, the interpretive frame determines the reference point against which outcomes are evaluated and whether distributive restraint is experienced as prudent stewardship or as an avoidable loss to an identifiable individual.

Prospect theory provides the core micro-foundations for why evaluations of distributive choices are reference-point dependent. The central insight is straightforward: individuals do not evaluate outcomes in terms of absolute final states, but as gains and losses relative to a reference point

(Kahneman and Tversky 1979, p. 263). The canonical value function is defined over these gains and losses; it is concave for gains, convex for losses, and steeper in the loss domain (Kahneman and Tversky 1984, p. 342). These properties imply diminishing sensitivity and, most importantly, loss aversion: losses loom larger than equivalent gains. Across decades of applications, reference dependence and loss aversion remain among the most robust regularities in decision-making (Barberis 2013). In healthcare rationing, this implies that the same funding decision can be understood either as avoiding a loss (e.g., not withholding a last-resort option) or as preserving a gain (e.g., protecting finite fiscal resources), and these alternative representations can generate systematically different preferences even when policy content is identical.

Reference points are not fixed; they are shaped by what people expect and by the information they receive. Research suggests that individuals form these reference points based on prior experience and communicated expectations (Koszegi and Rabin 2006). When outcomes are uncertain, people evaluate results not only in terms of utilities, but instead in terms of whether the outcome is perceived as a gain or a loss relative to those expectations, leading to systematic departures from expected utility even when probabilities are clearly stated (Koszegi and Rabin 2007). In policy environments, where information is mediated through institutional communication, the way a decision is described becomes part of how the reference point is formed. Kahneman's synthesis of judgment and choice highlights precisely this mechanism: framing affects what is treated as the baseline (i.e., reference point) and what is treated as a deviation from it (Kahneman 2003).

Healthcare rationing illustrates this clearly, as citizens may anchor on existing coverage, an identifiable patient, expectations of equal access, or the collective fiscal constraint. Loss aversion also implies a distinctive pattern of risk-taking. Because the value function is concave over gains and convex over losses, individuals tend to be risk-averse in the gain domain and risk-seeking in the loss domain (Kahneman and Tversky 1979, p. 273). For rationing decisions, this means that when an expensive medicine with uncertain benefit is framed as avoiding a salient loss, citizens should become more willing to accept risk and extraordinary expenditure; when framed as preserving gains by avoiding a costly and uncertain intervention, citizens should be more willing to endorse restraint. These patterns extend well beyond stylized laboratory settings. High-incentive experiments replicate the asymmetry in risk attitudes (Holt and Laury 2002), market studies document systematic deviations from neoclassical predictions when reference points are salient (List 2004), and extensions incorporating cumulative outcomes indicate that these mechanisms persist in complex environments where individuals evaluate sequences of decisions rather than isolated choices (Schmidt, Starmer, and Sugden 2008).

Prospect theory further suggests that individuals transform objective probabilities into decision weights, typically overweighting small probabilities and underweighting large ones (Kahneman and Tversky 1979, pp. 282–285). Combined with loss aversion, this produces the fourfold pattern of risk attitudes (Kahneman and Tversky 1984). In the context of oncology medicines, decisions often involve small probabilities of substantial benefit and high stakes; frames that render such possibilities salient can therefore be disproportionately persuasive. Importantly, these distortions are not confined to lay publics. Political elites and trained professionals also display systematic deviations from expected utility in prospect-theoretic directions (Linde and Vis 2017; Roisse Rodrigues Ferreira 2022; Abdellaoui, Bleichrodt, and Kammoun 2013). Thus, even when technical criteria are communicated with explicit probabilities, responses to uncertainty remain non-linear, leaving substantial scope for framing effects.

Reference dependence is reinforced by status quo bias and the endowment effect. Individuals defend existing arrangements more strongly than they pursue equivalent improvements because departures from the status quo are experienced as losses (Kahneman, Knetsch, and Thaler 1991, p. 197). Classic experiments suggest that simply owning an object changes how people value

it: individuals typically demand much more money to give up something they already possess (willingness to accept) than they would be willing to pay to acquire the same item in the first place (willingness to pay) (Knetsch 1989; Kahneman, Knetsch, and Thaler 1990, p. 1278), and related work suggests how allocation choices also follow from these dynamics (Thaler 1980). In healthcare, once expectations of access or coverage are established, withholding a medicine can be experienced as a loss relative to entitlement, even if the medicine is new or costly. Evidence from insurance demand similarly suggests that people value protection against losses more than equivalent gains (Hwang 2021). We suggest that in delegated settings, technical criteria do not eliminate these mechanisms; they provide one possible reference point that must compete with other salient baselines, including expectations of access.

Framing effects follow directly from these foundations because frames select and stabilize particular reference points. Mathematically equivalent choice problems generate systematic preference reversals when expressed in gain versus loss terms (Tversky and Kahneman 1981; Kahneman and Tversky 1984). In rationing contexts, public support can therefore shift when a decision is communicated as denying (loss) rather than not extending (a foregone gain), or as protecting the budget rather than withholding a last resort. The underlying mechanism is mental representation: individuals simplify complex problems through mental accounting, organizing outcomes around salient features of the frame (Kahneman and Tversky 1984, pp. 27–28). The same decision can thus be experienced either as an uncompensated loss or as an acceptable cost (Kahneman and Tversky 1984, p. 205). Because these representations are constructed, delegation that relies on technical rationales does not remove framing; it introduces additional material that can itself be framed and interpreted in different ways.

Recent work suggests why such effects should persist even when decisions are institutionally insulated from day-to-day electoral politics—that is, formally assigned to expert procedures and justified through technical criteria, yet still communicated to and evaluated by citizens in the public sphere. Framing operates through several mechanisms: it makes some considerations more salient, it activates emotional responses that shape evaluation, and it influences the inferences people draw about what a message implies and what the communicator intends (Flusberg et al. 2024, pp. 476–477). In risky-choice settings, affective responses are especially central to gain-loss framing (Flusberg et al. 2024, pp. 476–477). Experimental work in a public health crisis similarly finds that loss-framed messages intensify emotional responses and increase endorsement of riskier options (Hameleers 2020, p. 480). These mechanisms are not contingent on whether decisions are made by elected politicians or justified through technical criteria. They are features of how citizens interpret communicated information, including expert statements.

Heuristics amplify these effects under complexity. Judgment under uncertainty relies on representativeness, availability, and related shortcuts (Tversky and Kahneman 1974). The availability heuristic, in particular, implies that vivid, easily imagined cases weigh more heavily than abstract statistics (Tversky and Kahneman 1973). In rationing, a narrative of an identifiable patient denied a last-resort medicine is cognitively accessible, while diffuse opportunity costs borne by anonymous others are comparatively abstract. Political cognition research emphasizes that heuristics can economize on cognitive effort while also generating systematic biases and preference reversals (Lau and Redlawsk 2001). When citizens must evaluate technical criteria (thresholds, evidence summaries, probabilistic benefits), the temptation to lean on accessible cues increases, and frames shape which cues become accessible.

The contemporary information environment also matters because framing can be cumulative and competitive. Computational analyses suggest that repeated exposure to frames influences emotions and opinions over time (Guo, Su, and Chen 2025). During COVID-19, Valenzuela et al. (2021) document how competing economic and public health frames shaped support for restrictive policies,

with exposure to both economic and public health frames reducing support for mobility restrictions. Delegated healthcare rationing is similarly communicative: decisions justified through technical criteria are disseminated through institutional channels and interpreted in broader discursive environments. The implication is not that citizens cannot engage with technical justifications, but that what they take from those justifications is contingent on how those justifications are embedded in narratives and compared to salient counter-narratives.

Evidence from multiple policy domains reinforces the claim that framing is domain-general rather than an idiosyncrasy of healthcare. In education policy, how equity problems are labeled shapes support for interventions (D. M. Quinn 2025; D. Quinn 2025). In economic policy, the same wage floor can attract different support depending on whether it is presented as a minimum wage or a living wage (Schaitberger 2025). Media framing of job losses shifts blame attribution and policy preferences (Brutger and Guisinger 2025). Within health policy, even labels and wording can move preferences over implementation mechanisms (Roh and Niederdeppe 2016). Environmental policy further displays asymmetric gain-loss responses consistent with prospect theory (DeGolia, Hiroyasu, and Anderson 2019; Svenningsen and Thorsen 2021), while moralized framing can have intended and unintended effects (Troy, Eng, and Skurka 2025). Reference-point dependence extends even to “zero” outcomes, implying that what counts as losing versus gaining nothing is itself frame-sensitive (Wardley and Alberhasky 2021). Social policy experiments similarly report heterogeneous framing effects across populations (Asticher and Sager 2025). Taken together, these literatures imply that healthcare rationing should not be exceptional: when policy choices combine uncertainty, moral stakes, and complex trade-offs, framing effects are a predictable feature of mass evaluation.

Reference-dependent preferences are also well documented in adjacent decision domains characterized by insurance logic and intertemporal risk, which are conceptually close to public healthcare. Models of life insurance purchases grounded in prospect theory suggest that demand reflects loss aversion and reference dependence rather than expected utility (Pressacco 1984). Analyses of long-term care insurance uptake similarly suggest that present-oriented reference points and loss aversion can generate underinsurance against future risks (Meier 1999). Beyond risk with known probabilities, individuals display uncertainty and ambiguity aversion (Tsang 2020). These findings matter for rationing because the political dispute is rarely about a known lottery: it involves uncertainty about evidence, heterogeneity across patients, and ambiguity about long-run fiscal effects. Under such conditions, the reference point through which the decision is interpreted becomes even more consequential.

If prospect theory explains why the same trade-off can be represented differently, the rule of rescue explains why certain representations are uniquely potent in healthcare. The rule of rescue is the imperative to save identifiable individuals facing avoidable death even when doing so is inefficient and diverts resources from saving more lives elsewhere (McKie and Richardson 2003, p. 2407). It entails a preference for identifiable over statistical lives, a shock-horror response, and a prioritization of lifesaving interventions over non-lifesaving measures (McKie and Richardson 2003, p. 2407). In rationing, rescue narratives transform a distributional question into an evaluation of whether the state is allowing an avoidable tragedy. Importantly, rescue is not only about identifiability; narrative structure matters. Extensions argue that people are especially averse to depriving individuals of opportunities for narrative closure as they approach death (Sinclair 2022). In high-cost cancer contexts, even modest extensions of life can be framed as enabling closure, which can intensify the perception of loss if funding is denied. These features make healthcare particularly susceptible to loss frames that foreground identifiable individuals.

These theoretical strands yield a tight set of expectations for the empirical patterns our experiment documents. First, when an identical funding decision is framed as loss avoidance (especially when linked to an identifiable patient), loss aversion and the reflection effect imply greater willingness

to endorse risk and extraordinary expenditure. Second, when the identical decision is framed as gain preservation (protecting finite collective resources and broader access), reference dependence and status quo protection imply greater endorsement of restraint. Third, because rescue narratives intensify the moral salience of losses, they should magnify the impact of loss framing relative to more neutral presentations. Fourth, because framing operates through pragmatic inference, these effects should persist even when decisions are justified through technical criteria and even when authority is institutionally insulated Flusberg et al. (2024). In our setting, these expectations map directly onto the observed pattern: predicted support shifts across frames between (i) endorsing unconditional public funding, (ii) endorsing conditional funding tied to price reduction, and (iii) endorsing non-adoption, despite an identical clinical vignette. The broader implication is that technical criteria and institutional insulation operate within a framing-sensitive evaluative environment. Citizens may accept thresholds and evidence-based justifications in the abstract, but their concrete evaluations depend on the reference point activated by communication and on whether the situation is experienced as collective stewardship or as a morally charged failure to rescue. Under conditions of risk, scarcity, and uncertainty, the behavioral foundations of public evaluation imply that framing remains central to the politics of healthcare rationing.

3 Experimental Evidence on Framing and Mass Preferences in Delegated Healthcare Decisions

The empirical analysis draws on data from the 2021 Finnish Medicines Barometer, a national, cross-sectional population survey administered biennially by the Finnish Medicines Agency to examine experiences, opinions, and values related to health, medicines, and well-being. The 2021 wave included an ad hoc experimental module designed specifically to assess how citizens evaluate expert-justified healthcare funding decisions when identical cases are presented under alternative frames. This design directly reflects the theoretical framework developed above: in contemporary healthcare systems, reimbursement decisions are typically made through expert procedures and justified using technical criteria, yet they remain visible to the public and subject to mass evaluation. The survey questionnaire was drafted with influence from previous studies conducted in other countries, in particular the survey by Blendon et al. (2012), which similarly exposed citizens to real-life decision-making tasks, and Ghinea et al. (2021), which surveyed Australian citizens' attitudes towards public funding of high-cost cancer medicines.

Finland provides an appropriate research context for three reasons. First, the healthcare system is comprehensive and predominantly publicly funded, resembling other advanced welfare states in which questions of healthcare rationing and legitimacy are politically salient. Second, healthcare resource allocation decisions are routinely justified through clinical evidence, cost-effectiveness thresholds, and health technology assessment, making the communicative dimension of these decisions especially important. However, in contrast to many other countries with similar health systems, the justifications for reimbursement decisions of pharmaceuticals are confidential and thus in violation with the transparency criteria of legitimate limit-setting. Third, Nordic healthcare systems face precisely the structural pressures that motivate this study. Technological and demographic change contribute to a widening gap between medical opportunities and fiscal possibilities, which is a common source of controversy among stakeholders.

Data collection was carried out by a professional market research company (Taloustutkimus Ltd) using a pre-recruited online panel of approximately 40,000 Finnish citizens. To reach the target sample size, 10,105 invitations were distributed to panel members. The sample was stratified to ensure balance across gender, age, education level, and geographic region, with eligibility restricted to

Finnish-speaking citizens aged 18–79 years. The final analytic sample consists of 2,081 respondents, corresponding to a completion rate of approximately 20.6 percent. While online panels are not probability samples, stratification and quota-based recruitment ensure close correspondence with the Finnish adult population on key sociodemographic dimensions, making the data suitable for inference about mass public opinion in a welfare-state context.

The experimental module employed a randomized between-subjects design focused on framing effects. Respondents were randomly assigned to one of three conditions: a control condition and two treatment conditions that varied only in how the decision context was framed. All respondents received an identical clinical vignette describing a new oncology medicine characterized by high cost, uncertain benefit, and limited patient eligibility (Table 1). The vignette was drafted based on a published assessment by the Council for Choices in Health Care in Finland (COHERE Finland), with similar decision options that are used by their recommendations. COHERE, working in conjunction with the Ministry of Social Affairs and Health, only issues recommendations on including or excluding health technologies in the range of public health services. Decisions on reimbursement for outpatient medicines are conducted by the Pharmaceutical Pricing Board, also working in conjunction with the Ministry of Social Affairs and Health, and for inpatient medicines, the ultimate decision lies with hospitals. The framing manipulation consisted solely of additional information presented between the vignette and the decision task, allowing differences in responses to be attributed to framing rather than to substantive informational differences.

Following the vignette and framing manipulation, respondents were asked which decision regarding the medicine’s use they would find acceptable. Response categories captured increasing levels of cost containment: unconditional public funding, conditional funding tied to price reductions, rejection of funding, and an explicit “I don’t know” option. These categories map directly onto the theoretical expectations derived from prospect theory, as unconditional funding represents the most risk-acceptant position, conditional funding an intermediate position, and rejection the most risk-averse position.

To estimate the effect of framing on policy preferences, we model respondents’ choices using an ordinal logistic regression, reflecting the ordered structure of the outcome variable (Equation 1). The key independent variable is the framing condition, operationalized as indicators for the rule-of-rescue frame and the stewardship (utility-maximizing) frame, with the control condition as the reference category. The specification also includes demographic and socioeconomic covariates commonly associated with healthcare attitudes: gender, age, and income group, as well as indicators capturing health-related exposure, including eligibility for reimbursement of medicines and self-reported medicine expenditures. All models are estimated with survey weights to preserve population representativeness.

Formally, the estimated model can be written as:

$$\Pr(Y_i \leq j) = \text{logit}^{-1}(\tau_j - \beta_1 \text{LossRescue}_i - \beta_2 \text{GainsStewardship}_i - \gamma \mathbf{X}_i), \quad (1)$$

where Y_i denotes respondent i ’s preferred funding decision, ordered from unconditional funding to rejection; τ_j represents threshold parameters; Rescue_i and Stewardship_i indicate assignment to the loss-framed and gain-framed conditions, respectively; and \mathbf{X}_i is a vector of individual-level covariates including gender, age, income group, health status indicators, and medicine expenditures. Equation 1 therefore estimates how framing shifts the latent propensity to favor more restrictive funding positions, holding observed characteristics constant.

Table 1: Decision-making task administered in the survey with framing manipulation.

	Group A (rule-of-rescue frame)	Group B (health maximisation frame)	Group C (control)
Vignette	<p>Below, you will find a description of the benefits and costs of a new cancer medicine.</p> <p>Please read the description and then answer the question.</p> <p>There are annually 10 to 20 patients in Finland to whom the new medicine can be prescribed. The medicine does not cure cancer but a laboratory study has shown that it destroys cancer cells in about a third of the patients to whom the new medicine is given. It remains unknown if the new medicine extends patients' lives or if it improves their quality of life. The medicine comes with a great risk of adverse effects. If this new medicine is to be approved for use in Finland, its costs will be over 60.000 euros per patient at the final stage of cancer treatment.</p>		
Frame	<p>There is no cure for this particular type of cancer. The new medicine is a possible option for patients who have already received multiple treatments and for whom the remaining options are limited.</p>	<p>The funds available to healthcare are finite. The adoption of the new medicine means that the funds used to pay for it will mean cuts elsewhere in healthcare.</p>	<p>None</p>
Task	<p>What kind of decision regarding the new medicine's use would you find acceptable?</p> <p>Please choose the option that best reflects your opinion.</p> <ol style="list-style-type: none"> 1. The medicine should be adopted to use and paid by the society regardless of the price set on it by the pharmaceutical company 2. The medicine should be adopted to use and paid by the society if the pharmaceutical company lowers its price 3. The medicine should not be adopted to use and paid by the society 4. I don't know 		

Figure 1: Summary Statistics and Covariate Balance Across Framing Conditions in the Survey Experiment

Notes: The figure summarizes sample composition by experimental condition (Control, Loss/rescue, and Gains/stewardship). The age panel displays weighted kernel density estimates of respondents' age. The remaining panels report weighted percentages within each framing condition for the covariates used in the main model (Equation 1). All estimates use survey weights. The close overlap across conditions suggests good covariate balance from random assignment.

3.1 Results

After fitting Equation 1, we show Figure 2 which presents predicted probabilities for the three principal policy preferences across framing conditions (regression table shown in Table A1). The results reveal clear and systematic framing effects. Holding the clinical vignette, cost information, and decision task constant, respondents exposed to alternative frames shifted their preferred policy responses in substantively meaningful ways.

Figure 2: Framing Effects on Public Support for Funding a High-Cost Cancer Medicine

Notes: Points are predicted probabilities from the ordered logistic model (Equation 1; regression table shown in Table A1); vertical bars indicate 90% confidence intervals. The loss (rescue) frame increases support for unconditional funding and reduces outright rejection relative to the control, whereas the gains (stewardship) frame shifts support toward conditional funding and rejection.

The most pronounced pattern concerns support for unconditional public funding, the most risk-seeking option in the decision space. Consistent with the expectations derived from prospect theory, support for unconditional funding increases under the loss frame that emphasizes the absence of alternatives and the proximity of death, and decreases under the gains frame that emphasizes finite budgets and opportunity costs. Conversely, rejection of funding—the most risk-averse response—becomes more likely under the gains frame and less likely under the loss frame. Conditional funding occupies an intermediate position, absorbing shifts in both directions as respondents adjust their evaluations of fiscal risk.

Across conditions, the rank ordering of response options remains stable: unconditional funding is consistently most likely, followed by conditional funding, with outright rejection least likely. What changes is not the rank itself but the level of support attached to each option, as the frames sift probability mass across categories. In particular, the loss frame sifts support upward toward unconditional funding, whereas the gains frame sifts support away from unconditional funding and toward conditional funding and rejection. Thus, framing shifts the level of support across options

while preserving the same ordinal structure of preferences.

These results suggest that citizens do not evaluate reimbursement decisions solely in terms of technical information about clinical effectiveness or cost. Instead, preferences vary systematically with the reference point activated by communication (frames). When the decision is presented as avoiding a salient loss to identifiable patients, respondents appear more willing to accept financial risk and clinical uncertainty. When the same decision is presented as protecting existing resources for the broader patient population, respondents become more cautious and more supportive of restraint. The observed shifts are therefore consistent with the reflection effect and loss aversion predicted by prospect theory, as well as with the moral psychology captured by the rule of rescue.

Importantly, these effects emerge in a setting where respondents are not asked to act as policymakers but to evaluate a decision justified through information resembling real reimbursement debates. This feature of the design speaks directly to the institutional argument advanced in this article. The findings suggest that insulating reimbursement decisions from day-to-day electoral politics and grounding them in technical criteria does not eliminate the role of framing in shaping public evaluation. Citizens remain responsive to how choices are narrated, and their preferences display substantial elasticity even when the informational content of the decision remains constant.

We believe this elasticity has important implications for the legitimacy and contestability of healthcare rationing. Delegation to expert bodies may reduce direct political responsibility for specific reimbursement decisions, but it does not remove those decisions from the arena of public judgment. Instead, it shifts the locus of contestation toward communication, interpretation, and narrative framing. Public reactions to expert-justified decisions depend not only on the underlying evidence but also on whether the decision is understood as prudent stewardship of collective resources or as a morally troubling failure to rescue.

Taken together, the results provide empirical support for the theoretical claim developed in the previous section: reference-point-dependent evaluation and rescue-oriented reasoning persist even under institutional arrangements designed to depoliticize distributive choices. In contexts characterized by uncertainty, high stakes, and competing moral logics, framing remains a central mechanism through which citizens interpret and evaluate state action.

4 Appendix

4.1 Regression Model

Table A1: Framing Effects on Public Support for Funding Expensive Cancer Medicines

	Ordinal logit
Loss (rescue) frame (vs. control)	1.478*** [1.252, 1.746]
Gains (stewardship) frame (vs. control)	0.762** [0.644, 0.901]
Male (vs. female)	0.953 [0.830, 1.095]
Age	1.016*** [1.012, 1.021]
Income: middle (vs. low)	0.858 [0.719, 1.023]
Income: high (vs. low)	0.944 [0.778, 1.146]
Income: other/unknown	0.821 [0.652, 1.035]
Eligible for Kela reimbursement	0.977 [0.829, 1.151]
Num.Obs.	2458

Notes: Entries report odds ratios from an ordinal logistic regression. The dependent variable measures respondents' preferred funding decision for a novel, high-cost cancer medicine, ordered from unconditional public funding to outright rejection. The key independent variable captures experimental framing of the decision context. Control variables include gender, age, income group, education, eligibility for Kela medicine reimbursement, and self-reported medicine expenditure. Models are estimated using survey weights. 90% confidence intervals in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.
